Contents

- * Active carbon tests
 - * TOC reductions
 - * Effects on conductivity of water
 - * Silica
- * UV treatment tests
 - * TOC reductions
 - * Effects of number of UV lamps, wavelength, H₂O₂ and TiO₂ catalyst
- * LC-OCD measurement results

Active carbon tests: experimental set-up

Water treatment process of Stora Enso Oulu mill

Active carbon tests: experimental set-up

Test scheme of pilot scale AC filters.

Test scheme of full scale AC filters.

AC 1

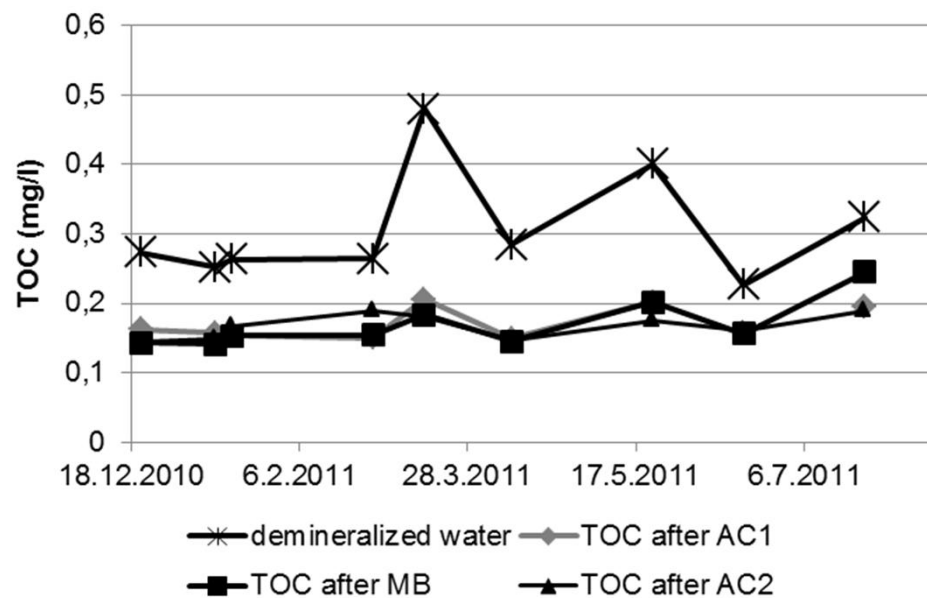

MB

AC 2

Active carbon: TOC reductions

Pilot scale AC filters

Residual TOC removal 38 – 57 %

Full scale AC filters

Residual TOC removal 40 – 65 %

Active carbon: LC-OCD results

(after ~ 10 months in use)

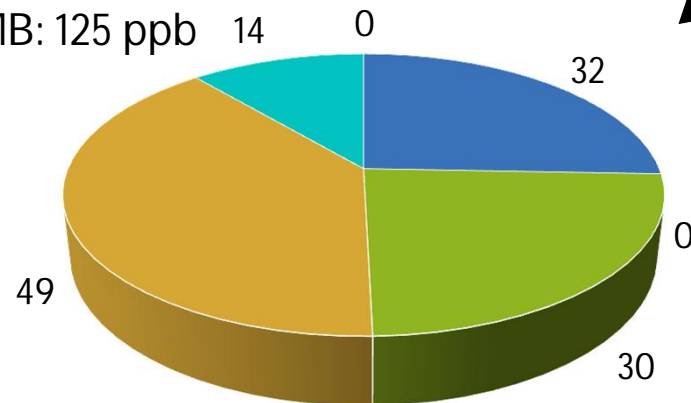

demineralized water: 155 ppb

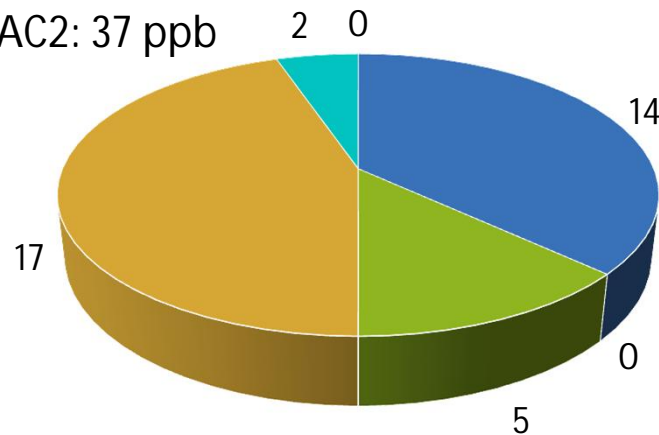

AC1: 62 ppb

MB: 125 ppb

AC2: 37 ppb

- hydrophobic
- biopolymers
- humic substances
- building blocks
- LMW neutrals
- LMW acids

AC vs. RO (LC-OCD)

AC + MB + AC: 37 ppb

RO (Ahlholmens Kraft): 42 ppb

AC: 62 ppb

- hydrophobic
- biopolymers
- humic substances
- building blocks
- LMW neutrals
- LMW acids

Active carbon: conductivity

Pilot scale AC filters and MB unit

Full scale AC filter

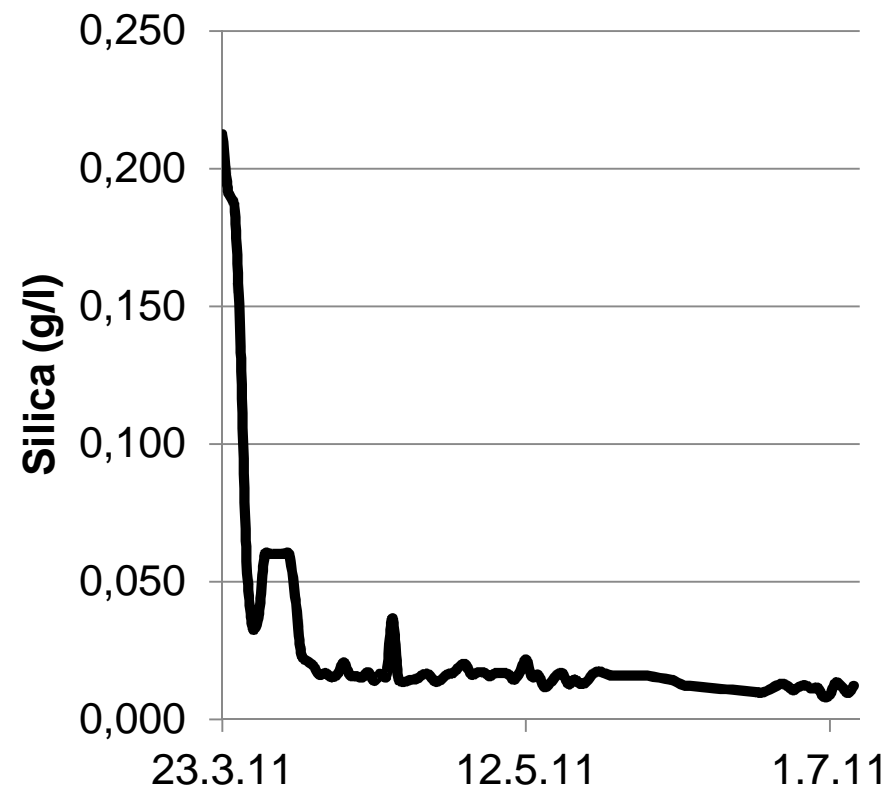

Active carbon: conductivity, some remarks

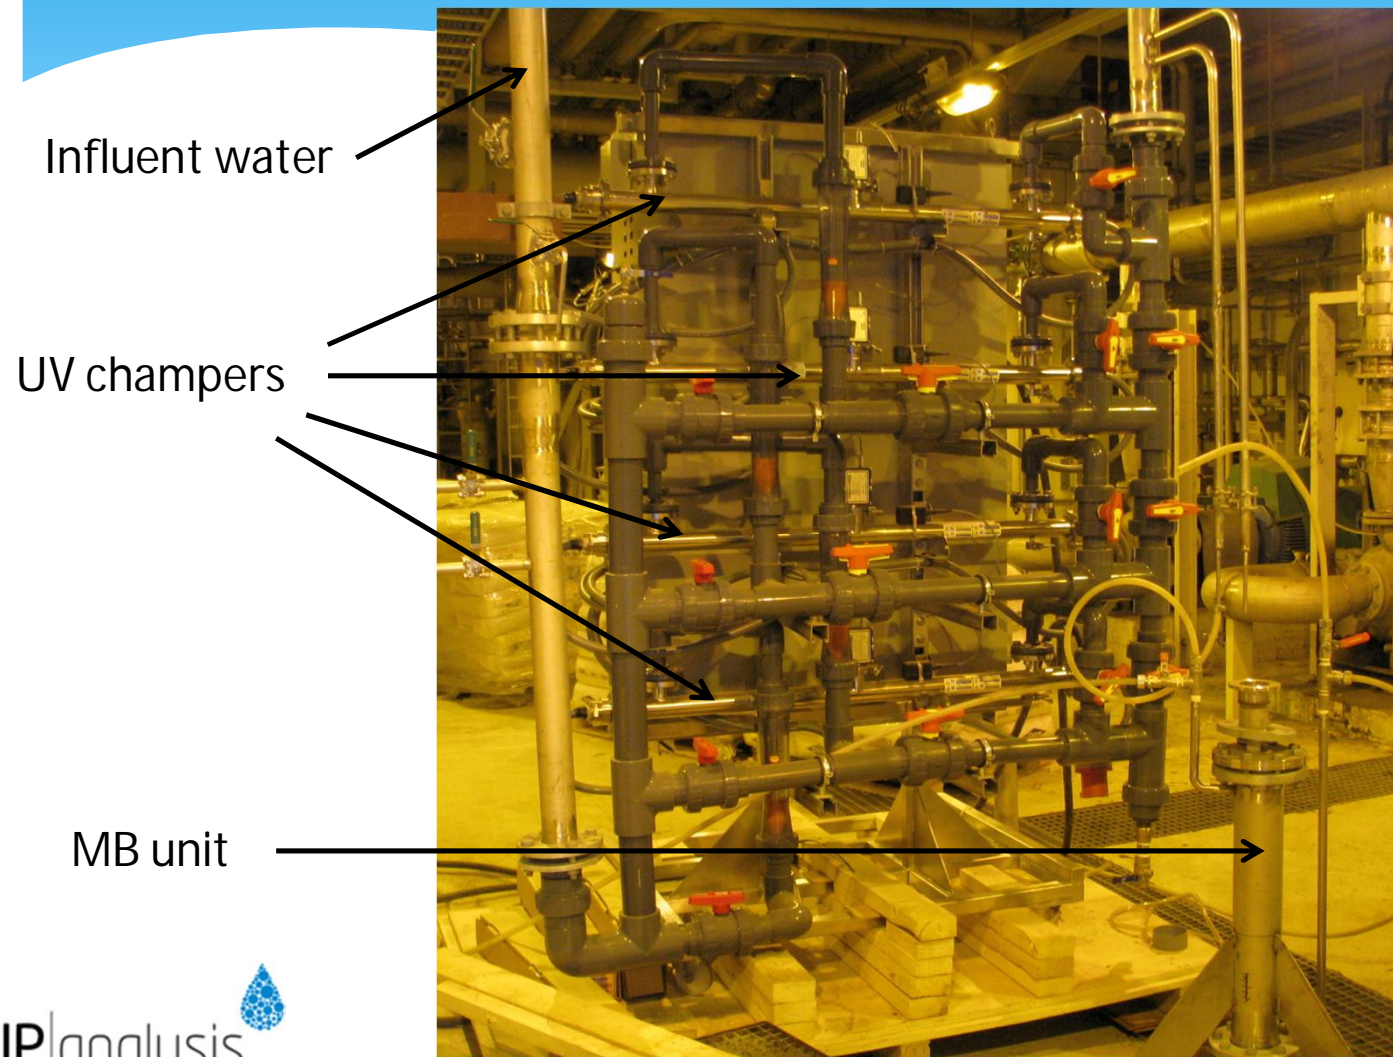

- * MB unit needed after AC to decrease conductivity
- * Correlation between TOC removal efficiency and conductivity was a bit unclear (linear R^2 only ~ 0,5)
- * Conductivity rise at AC bed was due release of ionized compounds from AC itself – not ionization of TOC
- * AC bed was not operating as biological filter because of low nutrient content of water

Active carbon: silica

- * Silica causes severe scale problems in water-steam cycle
- * Measured on-line during full scale test
- * New AC bed released silica for ~ 2 weeks
- * Silica was removed with subsequent MB

UV treatment: experimental set-up

UV treatment: results

- * One chamber: max. 30 % TOC removal
- * Four chambers: only 4 % increase in TOC removal
- * Effect of TiO₂ catalyst: negligible
- * Effect of H₂O₂: ? (experimental set-up failed: plastic piping released organic compounds)
- * Effect of wavelength:
 - * Medium pressure lamp (wavelength peaks at 254 nm and 185 nm): better (30 % TOC removal)
 - * Low pressures lamp (wavelength peak sharply at 185 nm): not that effective

TiO₂ catalyst

- * TiO₂ should enhance hydroxyl radical formation
- * This type of catalyst (porous net) had no effect

UV treatment: H₂O₂ dosing

H₂O₂ (35 %), elevated to ~ 40 m from dosing point

Flowmeter

- * Unknown peaks in LC-OCD chromatogram which are probably plastic additives

UV treatment: LC-OCD

demineralized water: 155 ppb

UV: 108 ppb

UV + MB: 113 ppb

- hydrophobic
- biopolymers
- humic substances
- building blocks
- LMW neutrals
- LMW acids

Conclusions: AC

- * Active carbon can remove up to 40 - 60 % of residual organic material (TOC)
- * AC bed lifetime before regeneration is at least 10 months
- * Subsequent MB is needed to remove elevated conductivity and silica
- * AC works fine in full scale

Conclusions: UV

- * UV treatment was able to remove up to 30 % of residual TOC
- * Removal efficiency did not improve with:
 - * Lower wave length (more energy)
 - * H₂O₂ (oxidant)
 - * TiO₂ (catalyst)
 - * Number of UV chambers (contact time)
- * Possible reason for this: water should be pretreated with e.g. RO (this is normal procedure in microelectronic or pharmaceutical industry water treatment)
